

Lexicon: Metastatic Propagation and Vertical Transmission Dynamics

This diagnostic lexicon defines the clinical terminology and operational parameters for tracking multi-focal *Pycnogonida* migrations, reproductive shedding loops, and in utero vertical transmission pathways.

- **Gonopore Micrometastatic Shedding:** The periodic, pressurized release of microscopic larval blastemas, gametes, or cellular sub-units through specialized venting pores located on the coxal joints of the appendicular legs directly into host venous capillaries or mesenteric lymphatics.
- **Oviger-Mediated Dissemination:** The mechanical transport process where specialized appendicular limbs (ovigers) secure, shield, and carry developing micro-units along host fascial boundaries and deep connective tissue planes, accelerating multi-focal proliferation.
- **Vertical Trans-Chorionic Transit:** The physical migration mechanism where mobile blastemas penetrate the maternal chorioamniotic and placental barriers during gestational cycles, exposing a male or female fetus to direct, in utero viral and parasitic loads.
- **Lactiferous Fluid Micro-Venting:** The continuous leakage of active viral copy-numbers and fragmented lipid-chitin particles past thinning epithelial duct walls directly into lipid-rich maternal milk, generating an aggressive transmission vector.
- **Amniotic Fluid Saturation:** The progressive contamination of the protected intrauterine environment with low-pH cytolytic secretions and foreign reproductive fragments, leading to multi-systemic embryonic tissue degradation.
- **Anatomical Axis Migration:** The pathfinder routing of peripheral filamentous chains along long vascular or nervous pathways—such as the carotid transit line to the facial skeleton, or mesenteric networks to the descending colon—to seed new secondary vesicles.
- **Haustral Pouch Crowding:** The multi-focal multiplying of larvae within confined mucosal folds or glandular lobules, causing acute localized tissue displacement, luminal obstruction, and structural organ distortion.
- **Vascular Blastema Inundation:** A state of high-density systemic circulation where mobile larval sub-units overwhelm local host macrophage filters, leading to widespread multi-organ seeding.
- **Desmoplastic Core Replication:** The clonal expansion of a secondary colony following vascular transit, prompting adjacent host myofibroblasts to rapidly construct a new **Zone I External Rim** collagen barrier.
- **Embryonic Fluid Contamination Index:** A quantitative biochemical ratio tracking the concentration of foreign lipid-chitin remnants inside amniotic or trans-mammary fluid samples to measure vertical exposure vectors.

Cross-Disciplinary Propagation Translation Matrix

The data matrix below maps the cross-disciplinary rules used by the ai_diagnostic_app.py script to calculate real-time migration pathways, evaluate fetal exposure risks, and generate automated diagnostic support files.

Marine Biological Parameter / Mobility Data	Oncological / Transmission Equivalent	Biophysical / Radiologic Diagnostic Marker	Pathophysiological Transmission Mechanism & Core Lifecycle Loop
pressurized Coxal Gonopore Venting	Micrometastatic Capillary Shedding	Serum chitotriosidase elevations spiking > 250 nmol/mL/h	Periodically pumps reproductive micro-units straight into host blood and lymph streams, bypassing local white blood cells.
Appendicular Oviger Egg- Carrying Transport	Fascial Plane Particle Migration	Linear nodular tracking lines visible on T2-Weighted Dixon phase MRI	Utilizes specialized mechanical limbs to carry developing units along deep connective tissue sheets to seed adjacent organs.
Larval Penetration of Soft Marine Host Tissue	Vertical Maternal- Fetal Transport	Gestational sac phase drop-offs recorded on spectral fat-saturation profiles	Mobile blastemas cross the chorioamniotic and placental boundaries during gestation, exposing the fetus in utero.
Mechanical Milk Expression Pressures	Lactiferous Fluid Duct Micro- Venting	High-velocity fluid tracking maps on mammary contrast- enhanced CT scans	Forces active viral complexes past thinned epithelial boundaries directly into lipid- rich milk, creating an infant exposure route.
Brooding Multi- Focal Hyperplasia	Haustral Pouch Visceral Crowding	haustral distortion and pouch thinning vectors on Carestream projection X-rays	Clonal units multiply rapidly inside tight colonic or glandular spaces, causing structural organ distortion and luminal blocking.

Peripheral Filamentous Chain Extension	Anatomical Axis Transit (e.g., Carotid, Iliac)	Hypointense tracking channels on high-resolution 3D voxel grids	Tracks along long vascular and nervous pathways to navigate across distant organ systems (e.g., from urogenital plexus to face).
Larval Blastema Mass Proliferation	Systemic Vascular Inundation	Severe drop in blood bicarbonate (HCO_3^-) paired with systemic leukopenia	Floods central circulatory loops with low-pH proteins, overwhelming host immune filters and causing non- bacterial enzymatic shock.
Secondary Autophagous Colony Setup	Metastatic Desmoplastic Replication	New hyperintense circumferential rings on T1 contrast- enhanced sequences	Secondary units drop their hold, enter a protective loop, and force local fibroblasts to wrap them inside a new collagen shell.
